## ANA-27: Sign-up Completion Analysis - Google vs Email

**Original Ticket:** When someone signs up on the website they can sign up with email or Google.

**Theory:** Users who sign up with email + password are less likely to complete sign up, primarily because coming up with a password is difficult.

**Question:** Is this true?

**Analysis Date:** 2025-06-25

**Data Coverage:** Complete historical analysis (March 2023 - June 2025)

**Analysis Scope:** 129,139 total sign-up events, 112,503 unique sessions

## Answer to Original Question

The Theory is FALSE

Email sign-up consistently **OUTPERFORMS** Google OAuth in completion rates

Method	Current Completion Rate	Historical Range	Speed
<b>Email</b>	<b>72.78%</b>	72-77% (stable)	6-14 minutes
<b>Google</b>	64.84%	50-77% (volatile)	0.8-3 minutes

### Key Finding: Password Creation is NOT the Barrier

1. **Email users are MORE likely to complete** despite password requirements
  2. **Google users abandon at higher rates** despite no password needed
  3. **The theory assumes password friction, but data shows the opposite**
- 

## Detailed Analysis

### Current State (Last 28 Days)

- **Email:** 1,881 starts → 1,369 completions = **72.78%** completion rate
- **Google:** 2,136 starts → 1,385 completions = **64.84%** completion rate
- **Advantage:** Email has **7.94 percentage point advantage**

### Historical Context

The pattern has been consistent throughout the analysis period: - **Email:** Maintains stable 72-77% completion rates - **Google:** Shows higher volatility (50-77% range) with periodic major drop-offs - **Baseline gap:** Even during Google's best periods, email typically performs equal or better

## Why This Contradicts the Password Theory

### 1. Speed vs Success Paradox

- **Google:** Faster process (0.8-3 minutes) but LOWER completion rates
- **Email:** Slower process (6-14 minutes) but HIGHER completion rates
- **Implication:** Password creation time is not the primary friction point

### 2. User Commitment Hypothesis

- **Email users:** Higher initial commitment threshold leads to higher completion
- **Google users:** Lower barrier to entry may attract less committed users
- **Result:** Easier start doesn't guarantee easier finish

### 3. Technical vs Psychological Friction

- **Expected:** Technical friction (password) should reduce completion
  - **Reality:** Psychological commitment may be more important than technical ease
-

## Volume Distribution Analysis (for EPD-1390)

### Current Proportions (Last 28 Days)

- **Google Sign-ups:** 2,136 attempts = **53.2%** of total volume
- **Email Sign-ups:** 1,881 attempts = **46.8%** of total volume
- **Total:** 4,017 sign-up attempts

### Historical Trends

Volume Distribution Over Time:

- Google consistently represents 52-58% of sign-up attempts
- Email represents 42-48% of sign-up attempts
- Google is the majority choice but not by a huge margin

### Business Impact of Volume Distribution

- **Google dominance:** Majority of users prefer Google OAuth
- **Performance gap impact:** Since Google has higher volume but lower completion rates, this compounds the business impact
- **Risk concentration:** Over 50% of sign-up success depends on Google OAuth performance

### EPD-1390 Implications

With Google representing **53.2% of sign-up volume**: 1. **Any Google OAuth improvements** have outsized business impact 2. **Google performance issues** affect majority of potential users 3. **Investment in Google flow optimization** should be prioritized due to volume

---

## Root Cause Analysis: Why Does Email Outperform Google?

### Problem Identification

Since the original theory (password difficulty) is disproven, we need alternative explanations:

#### 1. User Intent Differences

- **Email users:** Self-select for higher commitment (willing to create password)
- **Google users:** May be casual browsers taking the “easy” path
- **Quality vs Quantity:** Google attracts more attempts but lower-quality prospects

#### 2. Technical Implementation Issues

- **OAuth complexity:** More failure points than simple email form
- **Third-party dependencies:** Google API reliability, browser compatibility
- **Error handling:** Users may not understand OAuth failures as easily as form errors

#### 3. User Experience Problems

- **Permission requests:** May feel invasive or unclear
- **Redirect confusion:** Users may not understand OAuth flow

- **Trust issues:** Some users prefer direct account creation over third-party auth

## Historical Performance Degradation

- **Early 2023:** Google briefly matched email performance (75-77%)
  - **2023-2025:** Google performance declined while email remained stable
  - **Pattern:** Suggests something changed in Google implementation or external factors
- 

## Business Impact Analysis

### Current Loss Due to Incorrect Theory

By assuming email would perform worse, the business may have: 1. **Over-optimized Google flow** while neglecting email experience 2. **Missed opportunities** to improve the better-performing method 3. **Focused on wrong problem** (password friction vs OAuth reliability)

### Quantified Impact

- **Annual opportunity:** 2,200 additional users if Google matched email performance
- **Monthly loss:** ~183 users per month from performance gap
- **Volume-weighted impact:** Since Google is 53% of volume, improvements have major impact

### EPD-1390 Volume Insights

Google's **53.2% volume share** means: - **Investment in Google improvements** affects majority of users - **Google downtime/issues** impact most sign-up attempts - **Optimization priority** should focus on Google due to volume + performance gap

---

## Recommended Actions

### Immediate (Next 2 Weeks)

1. **Reverse assumptions:** Stop treating Google as the “better” method
2. **Audit Google OAuth flow** for technical issues and UX problems
3. **Implement monitoring** for Google completion rate drops
4. **Investigate error rates** and failure modes in Google flow

### Medium-term (Next Month)

1. **User research:** Why do email users complete at higher rates?
2. **A/B test Google improvements:** Simplify permissions, improve error handling
3. **Competitive analysis:** How do other companies handle Google OAuth?
4. **Consider hybrid approach:** Start with email, offer Google for convenience

### Long-term (Next Quarter)

1. **Goal:** Bring Google completion rate to email levels (72%+)
2. **Strategy:** Treat Google as the problem to solve, not the solution

3. **Measurement:** Target 75%+ Google completion rate with <5% volatility
- 

## Supporting Data

### Query Analysis Tools

1. **Current comparison:** `signup_completion_analysis.sql`
2. **28-day rolling trends:** `signup_completion_analysis_rolling_28d.sql` (1,578 windows)
3. **7-day rolling trends:** `signup_completion_analysis_rolling_7d.sql` (1,598 windows)
4. **Volume proportions:** `signup_method_proportions.sql`

### Key Metrics

- **Completion rates:** Primary success measure
  - **Volume distribution:** Business impact scaling
  - **Time-to-complete:** Process efficiency indicator
  - **Historical volatility:** Risk assessment
- 

## Conclusion

### Answer to Original Question

**The theory is definitively FALSE.** Email sign-up (with password creation) consistently outperforms Google OAuth by 5-10 percentage points. Password difficulty is NOT the primary barrier to sign-up completion.

### EPD-1390 Volume Analysis

Google represents **53.2% of sign-up attempts**, making it the majority choice. However, this volume advantage is offset by its **7.94 percentage point completion rate disadvantage**.

### Strategic Implication

The business should: 1. **Flip the optimization focus:** Improve Google OAuth, not email forms 2. **Question OAuth assumptions:** Faster does not equal better completion rates 3. **Investigate Google issues:** Technical problems, UX confusion, or user intent differences 4. **Leverage email success:** Study what makes email flow more successful

**Expected outcome:** Fixing Google OAuth to match email performance would add **2,200+ users annually** while improving the experience for the **53% of users who prefer Google sign-up**.

---

*Analysis completed using complete historical dataset: 129,139 sign-up events, disproving the original password-difficulty theory*
